(Part One)

INTRODUCTION

This catalogue in its first form was the result of my own needs soon after acquiring the sixinch Clark refractor in 1870. From the beginning that instrument was devoted almost entirely to the observation of double stars. Objects were constantly being found which could not be identified in any of the books at hand for reference, the principal one being an early edition of Webb's Celestial Objects. At this time there were but few books in Chicago bearing upon the subject of double stars. The old Dearborn Observatory, then under the directorship of Professor T. H. Safford, had a copy of Struve's Mensurae Micrometricae, some incomplete volumes of the Astronomische Nachrichten, and a few other works of minor importance. The small refractor showed many pairs, more or less difficult, which could not be found recorded in any of the available lists. At that time to make a complete catalogue of the then known double stars, it was necessary to first make pen copies of nearly everything required for this purpose. These were secured by visiting the libraries of the Naval and other observatories, and by borrowing the books from various quarters. In this laborious way manuscript copies were acquired of the material parts of nearly all publications relating to double stars. These copies included Struve's Mensurae Micrometricae, and Positiones Mediae; the Pulkowa Catalogue; the seven catalogues of Herschel II (Memoirs R. A. S.); the catalogues of Herschel, and Herschel and South (Philosophical Transactions); and a great number of minor lists and measures scattered through the volumes of the Philosophical Transactions, Memoirs and Monthly Notices of the Royal Astronomical Society, Astronomische Nachrichten; and hundreds of society, observatory, and other publications. In the course of time original copies of the more important of these works were picked up, and in the end a very complete library was formed of substantially everything relating to the known double stars. The manuscript general catalogue was kept continuously posted to date by the addition of all new stars and new measures from current publications. In order to make room for this new material, a second manuscript edition became necessary, and still later a third, which finally passed into the hands of the printer, and now appears in printed form.

The southern limit of -31° declination, adopted at the beginning, has been retained. includes all the stars that can be well seen at the principal northern observatories. But little had been done then, and the situation is sensibly the same at this time, in the way of a thorough examination of the southern stars, and in the measurment of those previously catalogued by Herschel and others. The northern heavens were much better explored when Struve's great work appeared in 1837 than the southern portion is now after an interval of seventy years, notwithstanding the labors of Tebbutt, Russell, Sellors, See, Innes, and others; and a general catalogue of the known objects at this time would be of as little use as a similar work for the northern sky would have been if prepared at the conclusion of the researches at Dorpat. It is possible that by the end of the present century, the information then given by an examination of the stars to the eighth magnitude, and by the necessary re-measurement of the old and other known pairs, may make it worth while collecting all the material into a single catalogue for reference, provided a few zealous observers shall arise with an undivided interest in this special work, and with suitable advantages in the way of telescopes and locations. have served no useful purpose at the present time to have extended the limits of this catalogue to the south pole. All that is needed in this direction at this time has been supplied by Innes who has compiled a provisional reference catalogue of the more prominent southern doubles, with measures of 1898, printed in the Annals of the Royal Observatory, Cape of Good Hope, Vol. II.

PART I. CATALOGUE

The page of the catalogue is made up of eleven columns as follows:

Column 1.—General number for reference.

Column 2.—Name of the double star. When found in other catalogues the synonyms are given in Part II.

Column 3.—Identification in the various star catalogues. Nearly all the double stars originally given in the several catalogues of the Herschels, the Struves, South and others, which are below the naked-eye limit, are not identified by the authors in any of the then existing star catalogues. So far as possible the stars which are bright enough to be included in any of the modern star lists are identified in one or another, and given in this column.

Columns 4 and 5.—Right Ascension and Declination. In the original manuscript catalogue, prepared more than thirty years ago, the places of the stars catalogued down to that time were carried forward to 1880. As the particular epoch used in a catalogue of this kind is a matter of no practical importance, these places have not been changed. At that time none of the catalogues of the Astronomische Gesellschaft had been published; otherwise the date adopted might have been 1875. The Durchmusterung epoch of 1855 would have served the same purpose, as no reduction is necessary, at least beyond a rough mental estimate, either in setting the telescope on any star in the catalogue, or in identifying any unknown object.

The places of the Struve stars were originally taken from *Positiones Mediae*, so far as they are found in that catalogue, but most of them have since been checked by the more recent observations in the modern catalogues. The Struve stars whose positions depend upon the approximate places in *Mensurae Micrometricae*, have all been identified in the *Durchmusterung* and other star catalogues. This has been done for all the Otto Struve stars, and as far as possible for all the stars in the lists of Herschel, South, and other early observers. Many of the objects in the seven catalogues of Sir John Herschel are too faint to be given in the *Durchmusterung* and other meridian lists. The others have been identified, and the corrected places given.

There is another class of double stars, principally from the observations of comparatively modern observers, where no attempt seems to have been made, beyond perhaps reading the coarse circles of the equatorial, to identify the star or give the exact place. As many as possible of these stars have been identified; others are not in or very near the given places; and still others obviously have large and uncertain errors of place which will make their identification hereafter a matter of accident or good luck.

There seemed to be no object to be gained by giving the right ascensions any closer than the nearest whole second of time, since as a matter of fact a large number of these stars have a much greater uncertainty in place from the lack of meridian positions, and from the lack of knowledge of their proper motions; and to give the right ascensions to small fractions of a second would imply an accuracy which would be unwarranted by the material at hand. This is also true generally of the declinations. While perhaps for a greater part of the stars, the nearest tenth of a minute of arc might have been given, it would have had no significance in the case of several thousand stars; and in any event would not have made the catalogue any more useful for any conceivable purpose, practical or otherwise. In any investigation concerning the proper motion, or the exact place of the star, the original catalogues of position will of course be consulted.

All of the stars are north of the equator, unless otherwise indicated by the minus sign attached to the degrees of declination. The advantage of the omission of the plus sign for the northern stars in rapidly finding any star, either north or south, will be apparent to those who have had to do this frequently in catalogues where all the signs are given.

Columns 6 and 7.—Position-angle and distance. The measures, unless otherwise noted, are from the original list referred to by the name of the star in column 2. For the Struve and Otto Struve stars the measures cited are by these observers. Nearly all the closer stars by Sir William Herschel are embodied in Struve's great catalogue. Those having distances exceeding the Struve limit, and which are not found in the later lists of Herschel II and South, are given with the

measures or description of Herschel I. Many of these have been identified for this work, and are given with corrected places. A few of the others, from lack or vagueness of description, can not be identified with any certainty.

The measures of Sir John Herschel as a rule are confined to a single setting for the position-angle, and an estimate of the distance. Generally these angles are in fair agreement with later measures when these stars have been re-observed. Change could only come from proper motion in pairs of this class. Later measures will show whether or not some of the apparent changes are real. Most of the Herschel estimates of distances are too large, and particularly of stars under 10".

Column 8.—Magnitudes. The magnitudes of the components are given from the same source from which the measures are taken. The scale employed by Struve, Otto Struve, Dembowski, and all the later observers is practically the same. That of Herschel II gives much higher numerical values for the magnitudes of telescopic stars. He gives the following corresponding values derived from a large number of comparisons of his estimates with those of Struve:

Η Σ	Η Σ	Η Σ
6.0 = 5.5 $6.5 = 5.9$ $7.0 = 6.4$ $7.5 = 6.8$ $8.0 = 7.3$ $8.5 = 7.7$ $9.0 = 8.1$ $9.5 = 8.5$	10.0 = 8.8 $10.5 = 9.1$ $11.0 = 9.3$ $11.5 = 9.6$ $12.0 = 9.8$ $12.5 = 10.0$ $13.0 = 10.2$ $13.5 = 10.4$	14.0 = 10.5 14.5 = 10.7 15.0 = 10.9 16.0 = 11.1 17.0 = 11.4 18.0 = 11.6 19.0 = 11.8 20.0 = 12.0

It is a fact worth noting that there is no satisfactory evidence of variability in the relative magnitudes of the components of any real double star, although distant stars have been occasionally connected with other stars in which there is some change.

Column 9.—Date of measures cited in columns 6 and 7.

Column 10.—The astronomer whose observations are given, and the number of nights on which complete measures were made. In many instances the angle was measured on other nights, which enter into the mean result given, but it cannot be presumed that they add much, if anything, to the value of the mean when the difficulty of the object, from the closeness or inequality of the components, made it impossible or undesirable to attempt measures of distance. The number of nights attached to the measures cited in Part II is that on which complete measures of angle and distance were made.

Column 11.—Brief notes relating to the several components connected with the principal star; the colors given by Struve for his stars, by Dembowski for the Otto Struve stars; and references to the original authority from which the pair is taken when there are no subsequent measures and the citation is brief enough to be given in this column. There is too much uncertainty in most of the observations of color, particularly of the smaller stars, and of the larger stars where the color is not of a decided character, to make it worth while giving any comparison of the various results which would necessarily present large differences.

APPENDIX TO PART I

While this work was going through the press, a great many new double stars were found by Aitken and Hussey at the Lick Observatory, which were received too late for insertion in their proper places in Part I. For the sake of completeness, and by way of bringing the catalogue of known pairs down to the latest date possible (1906), it seemed desirable to add these discoveries in the form of an appendix to Part I, and this has accordingly been done. The star places are for 1900, as given in the several *Lick Observatory Bulletins* from which they are taken.

PART II. NOTES TO THE CATALOGUE

In all cases where the stars have been reobserved since the observation recorded in Part I, a sufficient number of measures are cited, to show the motion, where there has been any relative change, and as far as possible its character, and to show the unchanged relation of the components where this seems to appear from the observations to this time. In many instances, and particularly of the Dorpat stars, where the observations extend over three-fourths of a century, perhaps the citation of a smaller number of measures would have answered every purpose, but it seemed best to give too many rather than too few. For obvious reasons only the best measures by the best observers are selected as a rule, and those made on a single night have been generally rejected except when there was nothing else in point of time to take their places. It must be clear to everyone that the omission of all indifferent and superfluous observations necessarily adds to the value and usefulness of this work. The author has not been handicapped or limited in any way as to space to be used; and in the citation of observations, and in the comments relating thereto, he has omitted nothing that in his judgment would be worth giving. It goes without saying that a large number of the published measures of double stars should be rejected in any investigation or discussion as to the relative motion of the components. There need be no difficulty or hesitation in deciding as to the proper material to be used. If all the observations, good, bad, and indifferent, are employed in the computation of an orbit, it is certain that the value of the result will be correspondingly impaired, and no method of treating the doubtful material will prevent this.

A liberal use has been made of diagrams to illustrate the motion shown by the observations. These are accurately drawn to scale with a protractor, devised for this purpose, having a 12-inch circle and graduated arm, allowing the angles and distances to be laid down at the same time. The original drawing is then reduced to the proper scale in the camera, and the negative used to transfer the picture by contact to the block for engraving. These diagrams, therefore, may be taken as perfectly representing the actual measures selected from the best available material.

It will be apparent to anyone who will take the time to examine a sufficient number of pairs which were measured by the early observers, that as a rule these observations are very rough and more or less uncertain, and with errors too large to permit of their use in investigating the relative motion of the components. With the crude micrometers, driving-clocks, and equatorial instruments of the early part of the nineteenth century, and previous thereto, it is perhaps remarkable that the measures of that time are as good as they are, and it is doubtful if the astronomers of this day could do any better work with such tools. But there are too many instances where these early positions are known to be erroneous, or only very roughly approximate, to make it safe to rely upon them in fixing the position and limit of the apparent orbit of a binary system. The uniformly reliable and accurate measures of double stars begin with the work of the great Struve in his *Mensurae Micrometricae*.

It is intended to give references to all the measures of each star, and to the more important papers relating to them. Doubtless some citations may have been overlooked, but it is not likely that many important omissions of this kind will be found. When there are no later observations, and the reference is brief, it is given in the last column of Part I. For this reason, many pairs which are likely to be of interest hereafter, are not represented by any note in Part II.

In a general way the references to published observations may be said to end with those received early in 1906, but owing to the time required to pass Part II through the press, some of the series of measures printed in *Astronomische Nachrichten*, *Monthly Notices*, etc., are cited where they come in the later hours of right ascension.

It will be seen that the micrometrical work on double stars since the observations of Struve has not been wisely distributed. A vast amount of time has been practically wasted in the duplication of measures of prominent and familiar pairs, and in observing objects which need no attention except at long intervals. Much more would be known at this time of most of the double stars if the observing lists had been more carefully selected during the last sixty years.

In order to make this portion of the work independent of the Catalogue (Part I) for general use and reference, the minutes and seconds of right ascension are given on the side, with the hour

at the top of each page, so that any star can be found when its general number or right ascension is known without first consulting the tabular part.

As far as practicable the proper motions of the principal stars have been taken from the best sources of information, and to make them immediately available for double-star purposes, the values from meridian observations in right ascension and declination have been reduced to arc, and given with the direction of the motion in position-angle. Many of these proper motions are small, and probably somewhat uncertain in amount and direction, but in some instances they are confirmed generally by the measures of the companion, or of some star in the field. When these measures are separated by a considerable interval of time, as they are in many of the old pairs, the proper motion thus found should be very exact. Most of the comparison stars are relatively faint, and may be considered as practically fixed in space. The instances where the small star has any sensible proper motion of its own are comparatively rare, so far as appears from micrometrical measures, and when a different value is found for the primary from observations connecting it with some small star, it would be unsafe in the great majority of cases to infer that therefore the comparison star was moving in space. Examples of stars of very different brightness drifting at practically the same velocity are not uncommon, and presumably they have some physical relation to each other, even when they are separated by distances considerably exceeding that of any of the known binaries.

It was my purpose to present in Part II late measures of every important star of the older catalogues, including all of the pairs in the Dorpat and Pulkowa catalogues, as well as all the stars of the several classes in Herschel I which were too wide to be included in the Mensurae Micrometricae, and like pairs in the lists of South, and Herschel and South, and also the most prominent stars in the seven catalogues of Herschel II which from the magnitude of the primary and the estimated distance between the components would presumably make them worthy of re-observation. In the interest of this work I have given something more than five years' time with the 40-inch at the Yerkes Observatory; and nothing in the way of other micrometrical work, however important it might appear to be in the line of other investigations, has been allowed to interfere with carrying out this programme.

As would be expected, the time which could be given to this work of 104 nights per year, making altogether only about 1,200 observing hours, assuming every night to be clear throughout, proved to be insufficient to complete the observations of so extensive a working-list, although some eight or ten thousand measures were made of these stars.

This part of this work is greatly indebted to Professors R. G. Aitken and Eric Doolittle for a large number of very recent and unpublished measures of classes of stars where late measures are specially important. The measures at the Lick Observatory are generally of very close and difficult pairs, many of them in rapid motion, and nearly all of the class which can be better measured at that place than anywhere else. The observations at the Flower Observatory are largely of the pairs discovered by Professor Hough at the Dearborn Observatory, many of which have not been measured since the first position was published. Professor Hussey, while at the Lick Observatory (1898 to 1904), made a large number of measures of the Struve stars which are still unpublished, and these are given in the notes; and also a few measures made at the Kirkwood Observatory, principally by Professors John A. Miller and W. A. Cogshall.

APPENDIX TO PART II

This contains very recent measures of neglected stars, and those having considerable relative motion, which could not be given in Part II. These observations were principally made at the Lick, Flower, and Yerkes Observatories, and include only those of pairs where late positions are important to the completeness of this work.

The Appendix also contains some measures from printed observations which were published after a portion of Part II was in type These include the first part of Doolittle's measures in *Publications of the Flower Observatory*, Vol. II, and a few measures by Biesbroeck, Espin and others.

The Greenwich New Reduction of Groombridge's Catalogue of Circumpolar Stars, received too late for use in Part II, contains a large number of proper motions not found in other catalogues, and the more important of these are given in the Appendix.

NUMBER OF DOUBLE STARS

The total number of real double stars now catalogued is necessarily very uncertain, and no safe approximation can be made, if this class is limited to physical systems, or those which are likely to belong to that order, judging from observations now made, the relative magnitudes and distances of the components, and their common proper motions where movement in space has been shown by meridian positions. It is certain that of the 13,655 stars contained in this Catalogue, at least several thousand are only optical or accidental pairs, and can have no physical relation to each other. This includes nearly all the pairs of Herschel II, as well as of Herschel I which are not included in Mensurae Micrometricae; many of the Struve and Otto Struve stars; and more or less from all the modern lists. The question of drawing some kind of arbitrary line between what might be presumed to be physical systems, and those which it was practically certain could not belong to that class, was considered at an early day in the preparation of this work. It was soon apparent from a practical application of the principles which were supposed to govern a judicious separation of the material into these two classes that it could not be successfully done. A too liberal application of the rule would reject a comparatively small number and so accomplish but little in reducing the size of the catalogue; while on the other hand a rigid enforcement would necessarily exclude many stars which are of some interest at least, in consequence of changes already shown from proper motion. Then again, the names of the great astronomers attached to these stars entitle them to a place in the first general catalogue of double stars, independent of any consideration of the stars themselves. I have therefore included them all, and as far as possible re-measured the large number of neglected pairs of the old observers for this work.

The distribution in the several hours of right ascension of the 13,655 stars north and south of the equator is shown in the following table:

R. A.	+ Decl.	— Decl.	Total	R.A.	+ Decl.	- Decl.	Total
Op	513	1 32	645	I2 ^h	257	I I 2	369
1	432	141	573	13	233	124	357
2	403	112	515	14	311	126	437
3	392	123	515	15	277	145	422
4	404	143	547	16	302	119	421
5 6	468	221	689	17	316	180	496
6	442	271	713	18	505	209	714
7 8	368	266	634	19	718	204	922
8	336	181	517	20	693	196	889
9	277	127	404	21	617	191	808
10	267	104	374	22	574	132	706
11	270	98	368	23	479	151	630
				Total	9,854	3,811	13,655

It would not be difficult, by a sorting-out and arrangement of the supposed classes of doubles with reference to the distribution in the heavens, to deduce various inferences based upon such statistics. But it seems certain at this time, with the extremely limited information furnished by all the discoveries and observations, that all such conclusions would be idle and useless. The time will doubtless come when the researches in stellar systems and stellar movements can be turned to good account in generalizations as to the construction and extent of the universe of stars. At present we know but little about less than two score of the binary systems, and practically nothing in detail of the hundreds and perhaps thousands of other pairs belonging to this class. The great majority of proper motions are more or less uncertain in direction and amount. With few exceptions, the dis-

tances from the solar system are wholly unknown, and are likely to remain so until by some new method the present errors of observation can be greatly reduced. In addition to all this it must be remembered that the apparent distribution of the stars in right ascension is influenced by conditions which have nothing to do with the real number of these objects, or with the actual number of stars catalogued in the given area. The season of the year when a particular part of the sky can be examined, particularly in the first half of the night, the length of the nights, the probable proportion of clear nights, and to some extent the mean temperature in the colder season, all have an influence on discoveries as well as measures. Practically nothing has been done in the way of finding close pairs in the stars below the ninth magnitude except at the Lick Observatory, and there it has been almost wholly confined to stars north of the equator. Only large apertures, in exceptionally favored localities, can successfully carry on such work. All the stars of this class are of comparatively recent discovery, and nothing is known as to what rank they will take in the physical class of double stars. At present all that is needed for all the double stars, old and new, and of all orders of brightness, is careful and systematic measurement. When this has been carried far enough to furnish the necessary facts, theories and speculations will be in order, and doubtless this part of the subject will be properly attended to by the astronomers of future centuries when it shall be warranted by the necessary preliminary work of their predecessors.

ORBITS OF BINARY STARS

In the indexes to the several classes of double stars will be found a list of 88 systems for which orbits have been found. Of this number only 34, marked (*), can be regarded as of any value. These may be considered as giving the periods and other elements with substantial correctness; but at the best they are only provisional, and will be supplanted at no very distant time by investigations based upon a continuation of careful and accurate measures of these systems. The observations of another half-century should determine the elements of all these orbits with very little error. As to the remaining 54 systems, the periods and all the elements of the orbits are wholly uncertain and worthless. They cannot be regarded as even approximations, since there is nothing in the given data to warrant a guess as to what will be the future relative motion of the components. In fact, in some instances it is not certain that they are physical systems at all. For anything that appears the change may be due to proper motion. Generally speaking, the arc described by the companion must be at least 270° to give results entitled to any confidence, but frequently this is insufficient, and in such cases nearly a complete revolution must be made before the apparent ellipse can be certainly known. When the described arc is short, the agreement of the observed and computed places does not even tend to prove that the deduced orbit is approximately correct, or anything like the real orbit. In such cases a great variety of ellipses, entirely dissimilar in all respects, will represent the observed positions equally well, and with errors of observation less than those which are probable in the measures by the best observers with the most complete and powerful equatorials. It did not seem worth while taking space to give the elements of these orbits, other than the periods. The place of publication is always cited, and the details of the results can be readily referred to.

BINARY SYSTEMS

The list of binaries does not include those for which orbits have been computed. It is evident that it is not easy to draw a sharp line between binary stars, and those which are probably binary. It is a matter of judgment, based upon the best observations, in reference to which opinions might well differ. The list of probable binaries might be very considerably extended by including many stars which are presumably physically related from the observed relative motion, and the closeness of the components. This is not a safe conclusion, whatever the probabilities may be in its favor. Stars which are widely separated now by reason of the proper motion of one of the components, at one time formed very close pairs, and the rapid angular change then might readily have been mistaken for orbital motion.

Many of the stars in these two lists, discovered in the last twenty or thirty years, have shown rapid motion, and it is probable that a good many new orbits can be investigated in the near future, if these stars, which are generally of the close and difficult class, are properly followed with the micrometer.

INDEXES

The index to the new stars discovered since Struve needs no explanation. These stars will be readily found by their numbers in Part I. The shorter and minor discoveries are given at the end in alphabetical order. The Struve stars are easily found in the catalogue or in the notes, except those which from precession or supplemental numbering are shifted from the regular numerical order, and these are given in the index with the corresponding general number in the catalogue.

As the prominent naked-eye stars are generally referred to by the constellation letters and numbers, and not by the corresponding double-star number, an index, with the constellations arranged in alphabetical order, is essential to the rapid finding of these stars in the catalogue without a knowledge of their right ascensions. Only the bright stars which are known by the Bayer Greek letter, or the Flamsteed number are given in the list. The few other doubles in the catalogue which are as bright as the sixth magnitude, but not included in the Flamsteed numbers, are not given, as they would necessarily be referred to by the double star lists from which they are taken.

These large stars appear in column 8 of the catalogue with the magnitudes assigned by the respective observers. In the index to the constellations the photometric magnitudes are given from the Harvard and Potsdam observations.

In this connection attention should be called to the careless and incorrect way in which the Bode constellation numbers are frequently printed in prominent astronomical publications. That number should always follow the name of the constellation, while the Flamsteed number should precede it. This correct method was established at least three-fourths of a century ago, but in recent years many writers have made no distinction, and have thus given the name of an entirely different star from the one referred to. Many of the double stars in this catalogue have the same Flamsteed and Bode numeral, as for example:

	Aquilan		~		NI.	0
	Aquilae			2424		8940
	Aquilae 11	=	Σ	2411		8878
20	Pegasi	=	Η	289		11428
	Pegasi 20	=	Σ	2799		11001
9	Cygni	=	Н	1493		9470
	Cygni 9	=	Σ	2496		9185
18	Cygni	=	Σ	2579		9605
	Cygni 18	=	Σ	2522		9305
49	Cassiopeiae	=	β	785		1051
	Cassiopeiae 49	=	Σ	30		205
32	Herculis	=	β	87 8		7 677
	Herculis 32	=	Σ	2024		7553

In certain parallax observations of Σ 2486, that star is often called 6 *Cygni*, in spite of the facts that 6 *Cygni* is one of the prominent stars of this constellation, is a double star of another class, and is more than 20° distant from the other. The Bode catalogue is no longer used for reference, but it is desirable to retain these numbers used by the old observers; and to avoid error and confusion they should be written as they were by these astronomers.

PRECESSION TABLES

It has been suggested that for the convenience of many persons who may use this catalogue, it would be desirable to add precession tables. Even if the limits of the page in Part I had permitted giving this information for each star, it would obviously be much better for all practical uses of the catalogue to give this in the present condensed form, which is sufficiently exact for the certain identification of every object in the sky, and in other star catalogues.

The tables for precession in right ascension (from 0° to 60° declination) are taken from the compilation and arrangement printed in *Publications of the Washburn Observatory*, Vol. I. The

precession in right ascension between 60° and 70° of declination, and precession in declination are derived from the tables given in Oeltzen's Argelander's Northern Zones (45° to 80°).

IN CONCLUSION

I wish to express my obligations to Professor George E. Hale for his friendly interest in this work, and his valuable aid in bringing about its publication; to the officers of the Carnegie Institution for their liberality in authorizing its presentation in printed form in the manner desired by the author; and to Professor Edwin B. Frost for his counsels and assistance during the prosecution of the observations at the Yerkes Observatory, and the passage of the manuscript through the press.

S. W. BURNHAM.

THE UNIVERSITY OF CHICAGO Yerkes Observatory, July, 1906.

- V. STARS PROBABLY BINARY
- VI. STARS OF THE 61 CYGNI TYPE
- VII. COMMON PROPER MOTION
- VIII. RECTILINEAR MOTION
 - IX. SUSPECTED OR DOUBTFUL PAIRS
 - X. BRIGHT STARS, WITH PHOTOMETRIC MAGNITUDES

I. STARS DISCOVERED BY MODERN OBSERVERS

		T. 3	SIAKS DISCOVERED BY MODERN OBSERVERS
